

LAB 4 REPORT

Name: Muhammad Sohaib

Reg No: 2026(S)CYS52

Lab Title: local and Global Variables

Theory: Local and Global Variables in Python are used to store data values inside a program. A **local variable** is created inside a function and can only be used within that function. A **global variable** is created outside a function and can be accessed throughout the program.

TASK 1:

```
x = 10 # Global variable
def show():
    print(x)
show()
```

Output:

10

TASK 2 :

```
def add():
    a = 5 # Local variable
    b = 3
    print(a + b)
```

add()

Output:

8

TASK 3

```
x = 20 # Global variable
def test():
    x = 5 # Local variable
    print(x)
```

```
test()  
print(x)
```

Output:

```
5  
20
```

TASK 4:

```
count = 0  
def update():  
    global count  
    count = count + 1  
update()  
print(count)
```

Output:

```
1
```
